

Buchwald-Hartwig Amination

Formation de liaisons C-N catalysée par le Pd, Cu, Ni

X = I, Br, Cl, OTf, etc.

Ligand = 1,2 et 3^{ème} générations

R₁, R₂ = Alkyle, aryle, H

Base = *t*BuONa, Cs₂CO₃

Cycle pallado-catalysé

Ligand biphosphine limite l'élimination bêta

Buchwald-Hartwig Alkoxylation (C-O coupling)

Formation de liaisons C-O catalysée par le Pd, Cu, Ni

RCM

ROM

Assez souvent la réaction se fait au reflux du dichlorométhane. Lors de la réaction il y a dégagement d'éthylène. Certains auteurs utilisent le benzène comme solvant.

Mécanisme de la réaction :

Cross Metathesis

Mécanisme : Chauvin (Nobel 2005)

Cycle catalytique

Features of Silicon Chemistry

I) GENERALITES

Structure électronique:
[Ne] 3s²3p²3d⁰

Une seule valence : 4

Spécificité de la chimie du Si

- Si est attaqué par des Nu
 - Si-O est facilement formée mais aussi facilement rompue
 - Si-F est extrêmement forte
 - Si-H et Si-C sont fragiles
- (donneur potentiel de R⁻ et H⁻)
- longueur Si-Z > C-Z
 - Stabilisation d'un carbanion en α

- Stabilisation d'un carbocation en β

Interaction entre σ C-Si riche et la p vacante
C δ^- -Si δ^+ : C = 2,50 Si = 1,74

Liaison	Energie de la liaison (kJ/mol)	Longueur de liaison (Å)
Si-C	318	1,89
C-C	334	1,54
Si-O	531	1,63
C-O	340	1,41
Si-H	339	1,48
C-H	420	1,09
Si-F	807	1,55
C-F	452	1,4
Si-Cl	471	2,02
C-Cl	335	1,74

Tsuji-Trost Catalytic Cycle

Carbonylative Stille Coupling

The mechanism is like that of a normal Stille coupling except that the carbon monoxide first exchanges for one of the phosphine ligands and then very rapidly inserts to produce an acyl palladium(II) complex. This then undergoes transmetalation with the vinyl stannane in the usual way forming trimethylstannyl iodide and the palladium complex with two carbon ligands. Reductive elimination gives the masked diketone and regenerates the palladium(0) catalyst. Transmetalation is the slow step in these coupling reactions so that there is time for the carbon monoxide insertion first. The final step—reductive elimination—releases the Pd(0) catalyst for the next cycle.

Jacobsen Epoxidation

Epoxydation des oléfines Jacobsen

The first report of epoxidation activity:

Kochi *JACS* 1986 (108) 2309.

Application en synthèse asymétrique (difficulté isomérisation cis-trans- mécanisme radicalaire!)

The Jacobsen epoxidation

Jacobsen *JACS* 1990 (112) 2801.

Jacobsen *JACS* 1991 (113) 6703.

Jacobsen *JOC* 1991 (56) 2296.

Jacobsen *TL* 1996 (37) 3271.

Mechanism

Proposed mechanism:

The S_N1 mechanism for nucleophilic aromatic substitution—**diazonium** compounds

When primary amines are treated with nitrous acid (HONO), or more usually with a nitrite salt or an alkyl nitrite in acid solution, an unstable **diazonium** salt is formed. You met **diazonium** salts in Chapter 22 undergoing coupling reactions to give aryl compounds, but they can do other things as well. First, a reminder of the mechanism of formation of these **diazonium** salts. The very first stage is the formation of the reactive species NO⁺.

The NO⁺ cation then attacks the lone pair of the amine and dehydration follows. The mechanism is quite simple—it just involves a lot of proton transfers! There is, of course, an anion associated with the nitrogen cation, and this will be the conjugate base (Cl⁻ usually) of the acid used to form NO⁺.

If R is an alkyl group, this **diazonium** salt is very unstable and immediately loses nitrogen gas to give a planar carbocation, which normally reacts with a nucleophile in an S_N1 process (Chapter 17) or loses a proton in an E1 process (Chapter 19). It may, for example, react with water to give an alcohol.

If R is an aryl group, the carbocation is much less stable (for the reasons we discussed earlier—chiefly that the empty orbital is an sp^2 rather than a p orbital) and that makes the loss of nitrogen slower. If the diazotization is done at lowish temperatures (just above 0°C , classically at 5°C), the diazonium salt is stable and can be reacted with various nucleophiles.

If the aqueous solution is heated, water again acts as the nucleophile and a phenol is formed from the amine. The aryl cation is an intermediate and this is an S_N1 reaction at an aromatic ring.

The point of this reaction is that it is rather difficult to add an oxygen atom to a benzene ring by the normal electrophilic substitution as there is no good reagent for ' OH^+ '. A nitrogen atom can be added easily by nitration, and reduction and diazotization provide a way of replacing the nitro group by a hydroxyl group.

Dihydroxylation des alcènes

Oxydant : KMnO_4 , OsO_4

Cis dihydroxylation de Sharpless (synthèse asymétrique)

Sharpless *JOC* 1992 (57) 2768.

General mechanism: Sharpless *Chem. Rev.* 1994 (94) 2483.

Evidence favors the [3+2] mechanism vs. [2+2]:
 Corey *TL* 1996 (28) 4899.
 Houk, Sharpless, Singleton *JACS* 1997 (119) 9907.

The enzyme-like binding cleft is especially well suited for π -stacking with aromatic substrates. Large rate accelerations are observed for aromatic substrates with the phalazine class of ligands.

Corey *JACS* 1993 (115) 2861, 12579.
 Sharpless *JACS* 1994 (116) 1278.

Iminium ions can also be formed by reducing amides with lithium aluminium hydride. A tetrahedral intermediate is formed that collapses to the iminium ion.

this metal could be aluminium or lithium:
it's not important to the overall mechanism
